October 18, 2020

What is a *function*?

An identifiable and reusable block of the source code. Its behavior can be influenced by parameters.

Why do we use functions?

- Long source codes can be made more transparent and comprehensible by grouping the related lines of source code in functions (modularity)
- Functions can be reused (called, invoked) several times instead of copy and paste code snippets (decreasing code size)
 - They can be applied in one, specific program to avoid the repetition of code fragments
 - or even in multiple programs to avoid the repeated preparation of frequently used code snippets (eg. `sqrt`, `printf`)

Function *definition*

- Providing all formal information about the function: type of the return value, name (identifier), arguments (formal parameters: variables that are going to store parameter values given at function call), body of the function (inside curly braces, see eg. `main`).
- Functions can be defined exactly once.
- Definitions can be placed in source codes or in precompiled libraries.

`absolute3.c`

```
3 double absolute(double number) {  
4     return number < 0. ? -number : number;  
5 }
```

Functions

Function call

- The function must be known at the place of call
- Passing control and (actual) parameters
- Call by *value*
- Returning program control and providing return value: `return`

absolute3.c

```
7  int main(void) {
8      double v;
9      printf("Enter a number: "); scanf("%lf", &v);
10     printf("Given number's absolute value: %f\n"
11            "absolute(-3) == %f\nabsolute(v*3) == %f\n"
12            "absolute(absolute(-3)) == %f\n",
13            absolute(v), absolute(-3),
14            absolute(v * 3), absolute(absolute(-3)));
15     return 0;
16 }
```

Return value

- Return type **cannot be an array**
- Expression after return: *assignment* conversion (a kind of implicit type conversion) may be required
- void: expresses the lack of return value (“procedure”)

Formal parameters (arguments)

- No information about the number of arguments: `int main() {...}`
- No arguments: `int main(void) {...}`
- One parameter: `double absolute(double number) {...}`
- Two parameters:
`double power(double base, double exponent) {...}`
- Actual parameters → *assignment* conversion → formal parameters
- Passing an array is a special case

Functions

The body of a function may contain everything that was allowed in the body of `main`, i.e.:

- Variable declarations
- References to items declared outside of the block
- Statements of activities

Returning from the function

- at the end of the function
- with a `return` statement (a function may contain several `return`-s)

`search.c` – Searching for the first occurrence of a character in a string

```
3 int search(char haystack[], char needle) {
4     unsigned i;
5     for(i=0; haystack[i]!='\0'; i++) {
6         if(haystack[i] == needle) return i;
7     }
8     return -1;
9 }
```

Functions

The definitions of functions **cannot be embedded!** (Except GCC, non-standard extension)

embedding.c

```
1 #include <stdio.h>
2 int main(void) {
3     double absolute(double number) {
4         return number < 0. ? -number : number;
5     }
6     printf("%f\n", absolute(-1.));
7     return 0;
8 }
```

Compilation error (GCC: warning)

```
embedding.c: In function 'main':
embedding.c:3:3: warning: ISO C forbids nested functions [-Wpedantic]
double absolute(double number) {
```

Assignment conversion

Occurrences: when assigning a value to a variable, eg.

- converting the return value of a function

`search.c` unsigned int \rightarrow signed int

```
3 int search(char haystack[], char needle) {
4     unsigned i;
5     for(i=0; haystack[i]!='\0'; i++) {
6         if(haystack[i] == needle) return i;
7     }
8     return -1;
9 }
```

Assignment conversion

Occurrences: when assigning a value to a variable, eg.

- when using the `?:` operator

uppercase.c `int` \rightarrow `char`

```
4  int main(void) {
5      char c;
6      printf("Character: "); scanf("%c", &c);
7      c = c>='a' and c<='z' ? c-'a'+'A' : c;
8      printf("Uppercase shape: %c\n", c);
9      return 0;
10 }
```

Assignment conversion

Occurrences: when assigning a value to a variable, eg.

- when converting the actual parameter of a function

absolute3.c `int → double`

```
3 double absolute(double number) {  
4   return number < 0. ? -number : number;  
5 }
```

```
13   absolute(v), absolute(-3),
```

Assignment conversion

Details: [C in a Nutshell](#)

Some examples:

From	To	Outcome
signed+	unsigned	✓
signed−	unsigned	loss of sign
long int	int	danger of loss of value
int	double	danger of loss of precision
float	double	✓
double	float	danger of loss of precision
double	int	truncatenation of the fraction part

Function usage example

Services (functions) to be implemented:

Combination A *k-combination* of a set S is a subset of k distinct elements of S . If the set has n elements, the number of *k-combinations* is equal to

$$C_n^k = \frac{n!}{(n-k)!k!} = \binom{n}{k}$$

Example: given *three* fruits (say an **apple**, a **pear**, and a **peach**) how many combinations of *two* can be drawn from this set?

- 1 **apple**, **pear**
- 2 **apple**, **peach**
- 3 **pear**, **peach**

Function usage example

Services (functions) to be implemented:

Factorial The factorial of a positive integer n , denoted by $n!$, is the product of all positive integers less than or equal to n .

$$n! = \prod_{k=1}^n k \text{ for all } n \geq 0 \text{ numbers.}$$

$0! = 1$ according to convention.

Most basic use \rightarrow Permutation: the number of possible distinct sequences of n distinct objects.

Example: how many distinct sequences of three distinct fruits (say an **apple**, a **pear** and a **peach**) can be created?

- ① **apple**, **pear**, **peach**
- ② **apple**, **peach**, **pear**
- ③ **pear**, **apple**, **peach**
- ④ **pear**, **peach**, **apple**
- ⑤ **peach**, **apple**, **pear**
- ⑥ **peach**, **pear**, **apple**

Function usage example

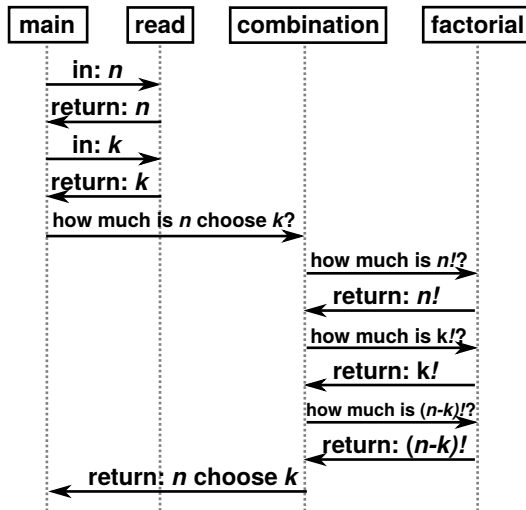

Services (functions) to be implemented:

Read The value of n and k must be read

Main Reading data, displaying $\binom{n}{k}$

Function usage example

Function usage example

nk1.c

```
1  #include <stdio.h>
2  #include <limits.h>
3  #include <stdbool.h>
4  #include <iso646.h>
5
6  int read(int max) {
7      int number;
8      bool invalid;
9      do {
10         printf("Number: "); scanf("%d", &number);
11         invalid = number<1 or number>max;
12         if(invalid) printf("Hibas adat!\n");
13     } while(invalid);
14     return number;
15 }
```

Function usage example

nk1.c

```
17 unsigned long factorial(int n) {
18     if(n < 2) return 1;
19     unsigned long f = 1ul;
20     for(int i=1; i<=n; i++) {
21         f *= i;
22     }
23     return f;
24 }
25
26 unsigned long combination(int n, int k) {
27     return factorial(n) / (factorial(k)*factorial(n-k));
28 }
29
30 int main(void) {
31     int n = read(INT_MAX);
32     int k = read(n);
33     printf("%lu\n", combination(n, k));
34     return 0;
35 }
```

Lifetime (duration): *a period during runtime* when the variable/function exists, allocates memory. Types:

- Static
 - From the beginning of program execution to its end
 - All functions and *global* variables (declared outside functions) have static lifetime
 - Global variables are implicitly initialized: all bits are set to zero
 - Preferably the usage of global variables **should be avoided**
 - + Time of parameter-passing can be saved
 - Hard to reuse code snippets, inflexible, environment-dependent code, danger of name conflicts, ...

Properties – lifetime

- Local
 - Allocates memory from entering the block until leaving it
 - Function arguments, variables defined inside blocks (eg. in a block of an if statement) have local lifetime
 - Only explicit initialization is possible

nk1.c

```
unsigned long factorial(int n) {  
    if(n < 2) return 1;  
    unsigned long f = 1ul;  
    for(int i=1; i<=n; i++) {  
        f *= i;  
    }  
    return f;  
}
```

17
18
19
20
21
22
23
24

Lifetimes (C99):

`factorial` exists during total program lifetime

`n` occupies memory 3x at the time of 3 function calls and frees memory at return (lines 18 and 23)

`f` occupies memory if `n` is great enough and cease at the moment of executing line 23

`i` occupies memory from reaching line 20 and cease when leaving the loop

Scope: a portion of the source code where a name can be used to access its entity.

- Block (local)
 - From the declaration to the end of the block it was defined, including embedded blocks, too.
 - Eg. formal parameters of a function and its local variables
- File (global)
 - Functions and all identifiers declared outside of functions; from the point of declaration to the end of the file
 - Eg. functions, global variables

Visibility:

- The portion of the source code where the name can be legally accessed, referred.
- *Scope* and *visibility* usually coincide, though an entity may become temporarily hidden by the appearance of a duplicate name. Both entities exist but the *name* cannot be used to access the *original entity* until the scope of the duplicate name ends → **creating duplicate names is a bad programming practice and should be avoided.**

scopeVisibility.c

```
1  int main(void) {
2      int i = 0;          // int i is in scope and visible
3      {                  // nested block
4          double i = 2.14; // i is local name in the nested block
5          i += 1;          // double i is in scope and visible;
6                          // int i is also in scope but hidden
7      }
8                          // double i is out of scope
9      i += 2;             // int i is visible and = 2
10 }
11 // int i and double i are both out of scope
```

Recursive function call

- All functions are allowed to call themselves directly or indirectly
- New memory areas are going to be reserved at every call for formal parameters and local variables
- Global variables remain at the same area
- Infinite recursion must be avoided!

nk2.c

```
1 unsigned long factorial(int n) {  
2     if(n < 2) return 1;  
3     return n * factorial(n-1);  
4 }
```

power1.c Calculating power with multiplications

```
3 long power(int base, unsigned exponent) {  
4     long result = 1;  
5     unsigned i;  
6     for(i=0; i<exponent; i++) {  
7         result *= base; }  
8     return result; }
```

power2.c Recursive power calculation, eg. $-3^5 = -3^{2^2} \times -3^1 = -243$

```
3 long power(int base, unsigned exponent) {  
4     long result;  
5     if(exponent == 0) return 1;  
6     if(exponent == 1) return base;  
7     result = power(base, exponent/2);  
8     result *= result; // We don't invoke it twice!  
9     if(exponent%2 == 1) result *= base;  
10    return result; }
```

Fibonacci sequence: each number is the sum of the two preceding ones, starting from 0 and 1. It counts the members of an imaginary rabbit family over time. How many pairs of rabbits will we have after n months if

- in the first month we only have 1 newborn rabbit-pair,
- newborn rabbit-pairs become fertile after 2 months,
- all fertile rabbit pairs give birth to another new pair of rabbits,
- and rabbits live forever :)

$$F_n = \begin{cases} 0, & \text{ha } n = 0 \\ 1, & \text{ha } n = 1 \\ F_{n-1} + F_{n-2} & \text{ha } n > 1 \end{cases}$$

The beginning of the sequence is: 0, 1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89, 144, ...

fibonacci1.c Iterative version

```
3 unsigned long fibonacci(unsigned month) {
4     unsigned long i=0, j=1, k;
5     if(month < 2) return month;
6     for(unsigned n=1; n<month; n++) {
7         k = i+j;
8         i = j;
9         j = k;
10    }
11    return k;
12 }
```

fibonacci2.c Recursive version

```
3 unsigned long fibonacci(unsigned month) {
4     if(month < 2) return month;
5     return fibonacci(month-1)+fibonacci(month-2);
6 }
```
